## Foreword

This publication, *Analysis of the Župna Cerkev Cemetery in Kranj (Slovenia): Final Report of the Research Project (Z6-4608): Data and Visualizations*, presents the analytical results of the project in a form intended to support both archaeological interpretation and methodological transparency. It is conceived not simply as a compilation of outputs, but as a documented account of how those outputs were generated, evaluated and understood. In the study of large medieval cemeteries with extensive stratigraphy, chronological interpretation depends not only on the quantity of excavated material, but also on the quality of documentation, the consistency of recorded stratigraphic relationships and the formal procedures through which heterogeneous data are integrated into a coherent analytical framework.

The present report is grounded in the development of Link[1], a digital analytical tool designed for the integration, cleaning, merging and visualization of complex stratigraphic and spatial cemetery data, as well as for chronological modelling based on graph representations derived from the Harris matrix.[2] In this respect, the report should be read not only as a presentation of data and visualizations, but also as a continuation of a broader methodological effort: namely, to formalize archaeological reasoning in a way that is computationally explicit, analytically reproducible and open to critical inspection. The Župna Cerkev cemetery in Kranj represents an especially demanding case study within this framework, owing both to the scale of the burial ground and to the density and complexity of its stratigraphic relationships.

A central issue in the present modelling concerns the temporal difference parameter (`td`) used within the Link[3] solving procedure. Archaeologically, this parameter is not intended to express an exact interval of 30 years between successive burials in a sequence, but rather a minimum temporal spacing used for modelling the chronological distance between consecutive burials in superposition. The operational value `td = 30` was adopted as an initial lower-bound assumption on the basis of previous research on comparable burial contexts and is discussed in greater detail elsewhere.[4][5] This distinction is important: the model does not claim that one knows an exact interval of 30 years between successive burials, but only that the chronological separation should not be modelled as less than this lower threshold. In practice, the actual interval may of course be substantially longer, including in some cases many decades or even centuries, which is entirely consistent with the long-term use of cemetery space.

For this reason, `td = 30` was treated here as a starting hypothesis within a broader parameter sweep rather than as a definitive prior. The model was run across the integer interval from 1 to 100 in order to assess whether the available stratigraphic and chronological constraints from the Župna Cerkev cemetery would produce convergence toward a narrower and internally coherent range of admissible values. This step is methodologically essential, because it shifts the discussion away from the defense of a preferred parameter and toward a more rigorous question: whether the archaeological dataset itself is sufficiently informative to constrain the solution. At the same time, the constraining power of the model depends directly on the quantity and quality of chronological evidence available within individual burial sequences. Where chronological indicators are absent or sparse, the behaviour of the model necessarily becomes less sharply resolvable.

This issue is particularly important in the case of the Župna Cerkev cemetery because the evidential structure differs across periods. For the early medieval horizon, chronological modelling is supported by a comparatively richer body of datable grave goods and associated chronological indicators. By contrast, in the high and late medieval sequences, grave inventories become extremely sparse and in many cases are almost entirely absent. As a result, these later burial sequences often remain chronologically underdetermined, with fewer independent anchors available for testing the temporal behaviour of the model. In such cases, sensitivity analysis remains methodologically valid, but the archaeological record provides less leverage for discriminating sharply between competing values of `td`.

A simple theoretical consideration further clarifies why the value of 30 years should be understood as a minimum rather than as an exact expectation. Within the currently defined chronological frame of burial activity at the site, bounded in the present model by the anchor points `T/G = 700--1798`, a single burial location reused at perfectly regular intervals of 30 years could in theory produce approximately 37 successive superpositions over the full duration of cemetery use. In reality, the observed stratigraphic sequences are far shorter, most commonly in the range of roughly 5 to 15 superposed burials. Archaeologically, this discrepancy supports the interpretation that 30 years functions as a conservative lower bound and that the effective interval between successive burials in the same location was often considerably greater.[6] The aim of the model is therefore not to enforce an implausibly precise periodicity, but to introduce a formally testable minimum temporal separation within the logic of the chronological solution.

The fact that the present results remain inconclusive across the tested range should therefore not be taken as evidence against the validity of the method. Rather, it indicates that the current excavation record does not provide enough resolving power to discriminate sharply between competing `td` values in a consistent manner across all sequences. In other words, the limited degree of convergence observed here is a property of the evidential structure of the dataset, not a failure of the computational logic. With denser, cleaner and more stratigraphically informative data, one would expect the evaluation curves to tighten and a narrower zone of

convergence to emerge within a more restricted interval. Accordingly, the present analysis should be understood not as an attempt to defend a preconceived `td` value, but as a formal sensitivity analysis showing that meaningful chronological convergence is contingent upon the quality and resolving power of the underlying archaeological record.

The current implementation of the model also operates within explicit chronological anchor limits for the beginning and end of burial activity, presently set to 700 and 1798. These boundary conditions were established on the basis of the analysis of the stratigraphically earliest graves and the reconstructed onset of burial activity at the site.[7] They should therefore be understood as analytically defined working bounds within the present stage of research, not as immutable chronological closures. One of the principal strengths of the Link[8] framework is precisely that newly available chronological evidence can be incorporated into the model and processed each time through the same transparent and verifiable procedure, thereby generating revised outputs in a consistent and reproducible manner.

In this sense, the report should be read both as a presentation of results and as a demonstration of method. Its aim is not to create an appearance of certainty where the archaeological record cannot sustain it, but to make explicit the extent to which chronological inference can be supported by the available evidence. The visualizations and datasets assembled here are therefore not merely documentary outputs; they also form part of a broader methodological argument. They show how computational modelling, when applied transparently and critically, can clarify both the possibilities and the limits of archaeological chronology in contexts of extensive cemetery stratigraphy. Future chronological refinements, whenever they become available, will be integrated and published through the same analytical workflow and the resulting data will remain publicly accessible through Link.[9]

# Temporal Analysis

## Burial Arm Positions over Time

Each burial was assigned a temporal position by calculating the midpoint of its dating range $(t_{from} + t_{to})/2$ and grouping the result into 50-year bins. Only burials with a positive dating span of 400 years or less were included to reduce the influence of poorly constrained dates. Arm position is recorded as a two-digit code, where the first digit encodes the left arm and the second digit encodes the right arm. Valid positions range from 1 to 8. Burials with missing or out-of-range arm codes were excluded. The figures and tables below show how burial arm positions vary over time, using column-normalized percentages to represent the relative frequency of each arm position within a given time bin.

Based on n=472 burials, timespan ≤ 400 years.

### Range of Item (Shape) Types over Time

Items were extracted from all graves, excluding finds from backfill contexts. Two dating sources are distinguished: standard chronological dating (blue) and C-14 dating (green). In both cases, only graves with a non-negative dating span of 200 years or less were included. Each horizontal line represents the chronological range of a single grave containing a given item. Items are grouped by type and subtype, with each combination shown as a separate figure.

Based on n=1012 items, dating span ≤ 200 years.

### Distribution of Item Types over Time

Items were joined to their parent graves and filtered to exclude backfill contexts. Only graves with a non-negative dating span of 400 years or less were included. Each item's dating range is expanded into 50-year bins, and the heatmap shows how item types are distributed over time by counting items per type within each bin. Only the most frequent types (top 50 by count) are shown.

Based on n=1742 items (top 50 types), timespan ≤ 400 years. Heatmap uses 50-year bins.

Based on n=1742 items (top 50 types), timespan ≤ 400 years. Table uses 100-year bins for readability on A4.

## Orientation Analysis

Only burials with a non-negative dating span of 400 years or less and a recorded grave orientation (azimuth) greater than zero were included. Each burial was assigned a temporal position using the midpoint of its dating range $(t_{from} + t_{to})/2$ and grouped into 50-year bins.

### Burial Orientation over Time

Burial orientations were grouped into 20° azimuth intervals. The heatmap shows how these orientation classes are distributed over time.
Based on n=808 burials, timespan ≤ 400 years.

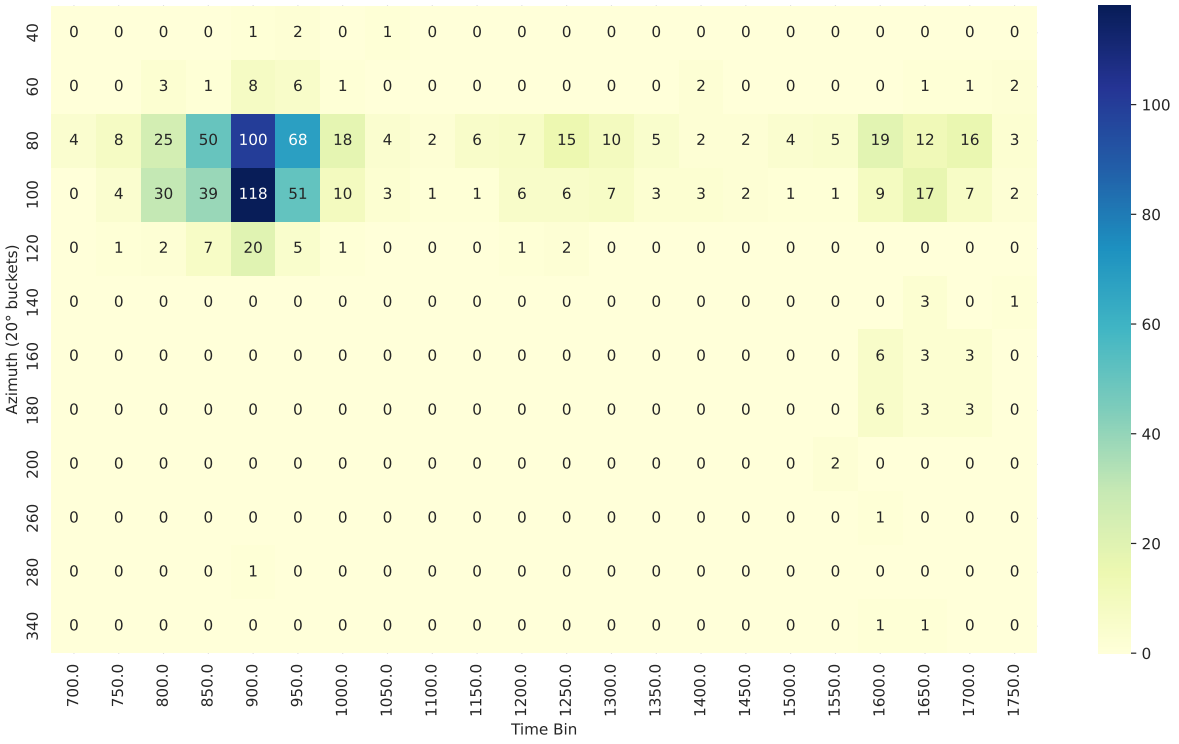

Figure 177: Burial orientation over time (20° azimuth buckets).

Based on n=808 burials, timespan ≤ 400 years.

### Orientation Clusters over Time

To identify orientation groupings, azimuth was decomposed into its sine and cosine components to preserve circularity, then combined with the temporal midpoint and standardized using z-score normalization. K-Means clustering ($k$=3) was applied to these three features to identify groups of burials with similar orientation and temporal placement.
Based on n=808 burials, timespan $\leq$ 400 years.

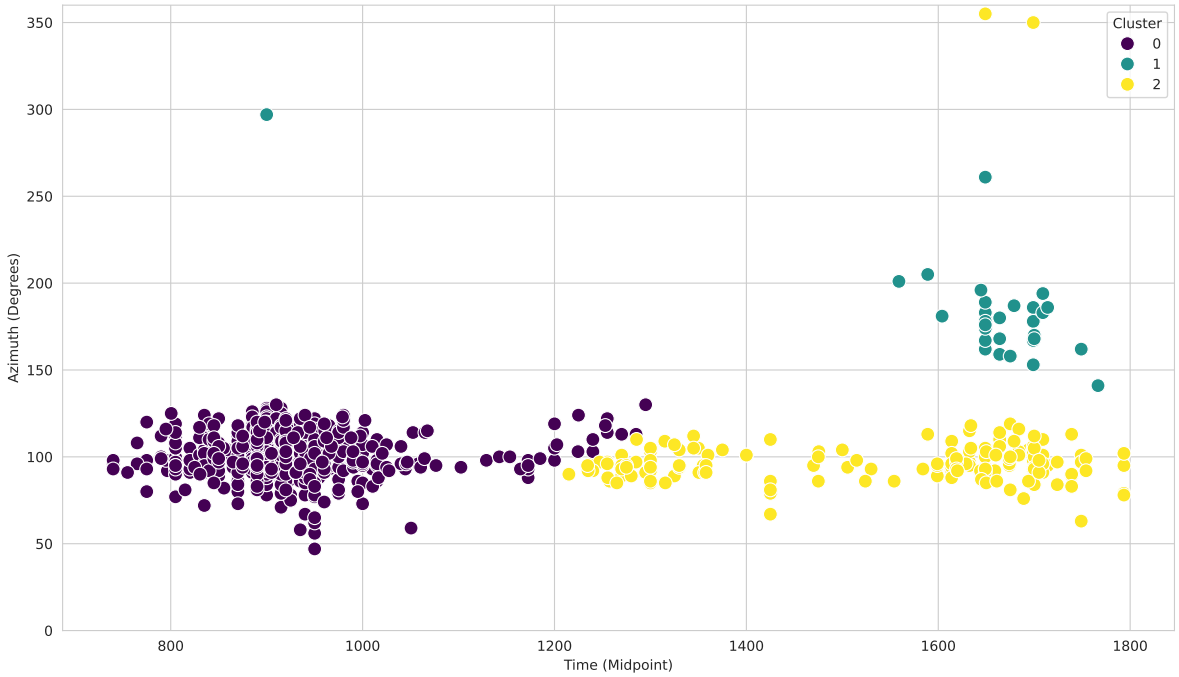

Figure 178: Burial orientation clusters over time (k=3).

### Polar Projection of Burial Orientation

The polar projection maps burial orientation to the angular axis and time to the radial axis, with earlier burials near the center and later burials toward the edge.
Based on n=808 burials, timespan $\leq$ 400 years.

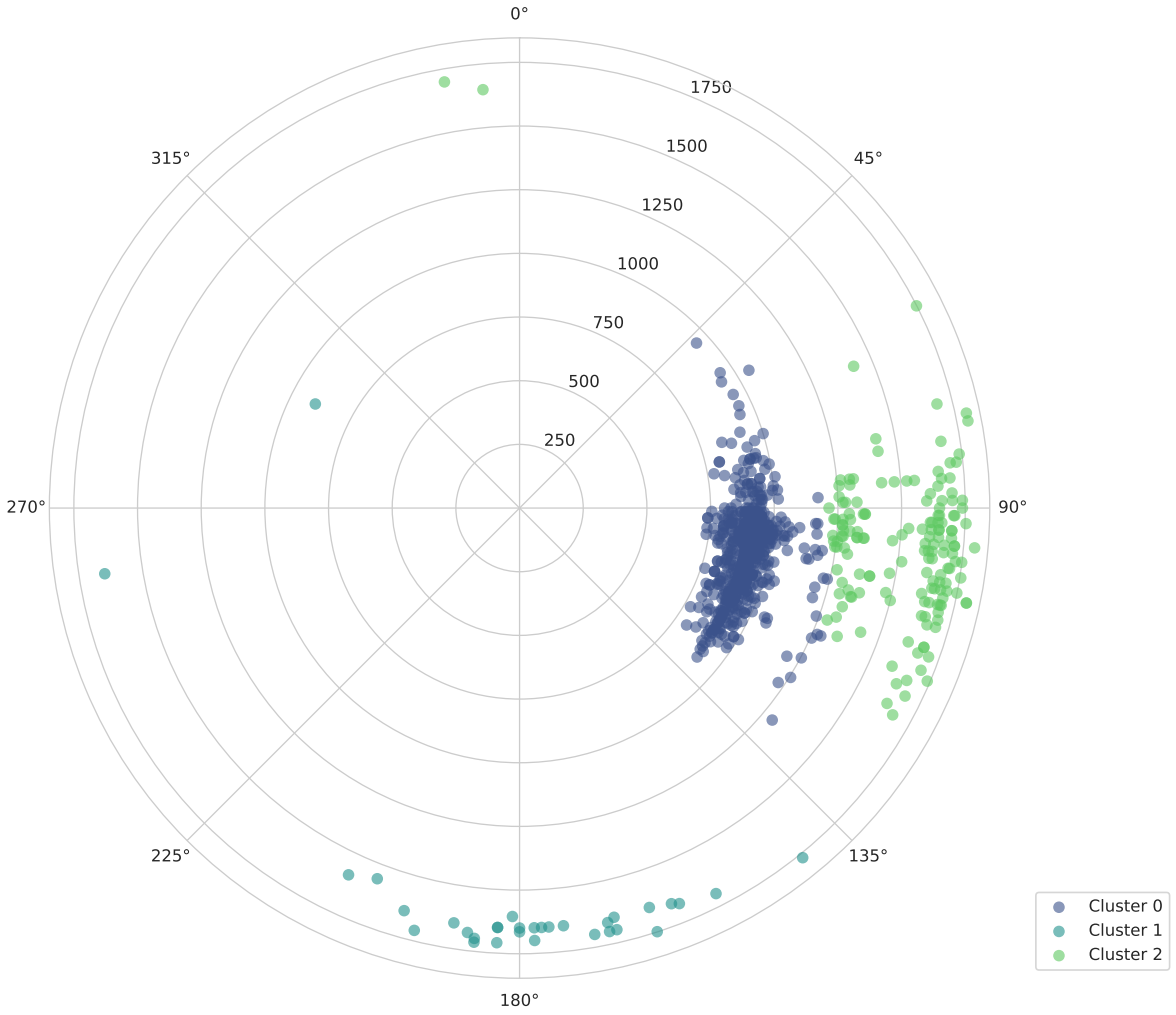

Figure 179: Polar projection of burial orientation over time (center=earliest, edge=latest).

### Temporal Correlation of Burial Orientation

The correlation matrix reports Pearson coefficients between temporal position and the circular components of burial orientation (sine and cosine).
Based on n=808 burials, timespan $\leq$ 400 years.

## Spatial Analysis

Only burials with a non-negative dating span of 200 years or less and valid spatial coordinates ($x > 0$, $y > 0$) were included in the spatial analysis. Each burial was assigned a temporal position using the midpoint of its dating range $(t_{from} + t_{to})/2$. Most spatial trend plots below use 100-year (century) intervals, while the sector heatmap uses earliest burial years grouped into 50-year bins.

### Cemetery Layout

The scatter plot displays individual grave locations with color encoding derived from the estimated temporal midpoint. The kernel density estimation highlights areas of concentrated burial activity, with contour levels indicating relative intensity. Together, these two views provide an overview of the spatial extent and density distribution of the cemetery.
Based on n=612 burials, timespan $\leq$ 200 years.

### Earliest Burial Years by Sector

The cemetery is divided into square sectors of 4 coordinate units along both axes. For each occupied sector, the earliest burial year is identified using `ts_from`. The heatmap colors group these earliest years into 50-year bins to highlight broader chronological patterning, while the cell annotations retain the raw earliest burial year for each sector.
Based on n=612 burials, timespan $\leq$ 200 years. Sector size=4 coordinate units; colors show earliest burial years grouped into 50-year bins, and cell labels show the raw earliest year in each sector.

### Shift in Burial Activity over Time

The centroid of all burial locations was calculated per century by averaging the $x$ and $y$ coordinates of all graves within each 100-year bin. These centroids are connected in chronological order to visualize the directional movement of burial activity over time. Individual graves are shown in the background for spatial context.
Based on n=612 burials, timespan $\leq$ 200 years.

### Spatial Expansion of the Cemetery

Each panel shows the graves active during a single century highlighted in red, with all other graves shown in grey for context. The black cross marks the centroid of the active graves in each period. This small-multiples layout allows direct comparison of the spatial extent and density of burial activity across centuries.
Based on n=612 burials, timespan $\leq$ 200 years.

## Demographic Analysis

Only burials with a non-negative dating span of 400 years or less and an identified gender (M or F) were included in the plots. Each burial was assigned a temporal position using the midpoint of its dating range $(t_{from} + t_{to})/2$ and grouped into 50-year bins. The subsections below examine how gender representation, burial treatment, and age at death vary by gender and, where applicable, over time.

### Gender Distribution over Time

The gender composition of the burial sample is shown both as absolute counts and as column-normalized percentages across time bins. The normalized view reveals shifts in the male-to-female ratio over time independent of overall burial frequency.
Based on n=733 burials with identified gender (of 1158 total), timespan $\leq$ 400 years.

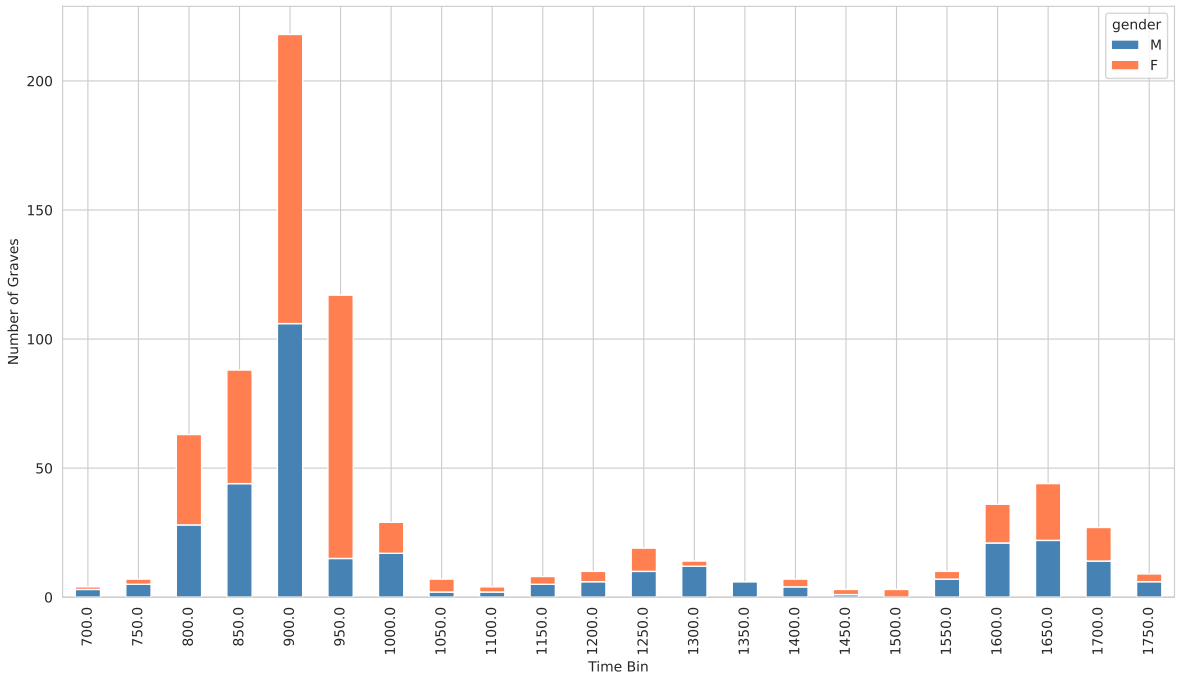

Figure 196: Gender distribution over time (absolute counts).

Based on n=733 burials with identified gender (of 1158 total), timespan ≤ 400 years.

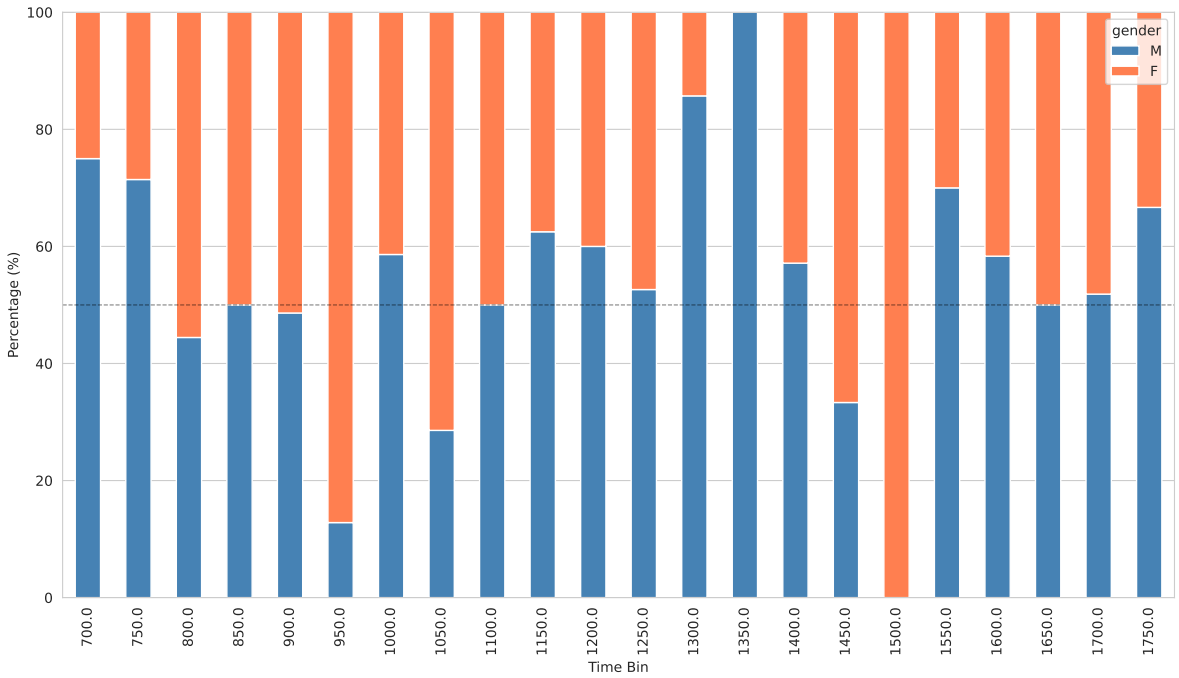

Figure 197: Gender distribution over time (normalized %).

### Burial Depth and Grave Orientation by Gender

Burial depth and grave orientation are compared between genders using box and violin plots respectively. Differences may indicate gender-specific burial conventions or spatial zoning within the cemetery.
Based on n=733 burials with identified gender (of 1158 total), timespan $\leq$ 400 years.

Based on n=733 burials with identified gender (of 1158 total), timespan ≤ 400 years.

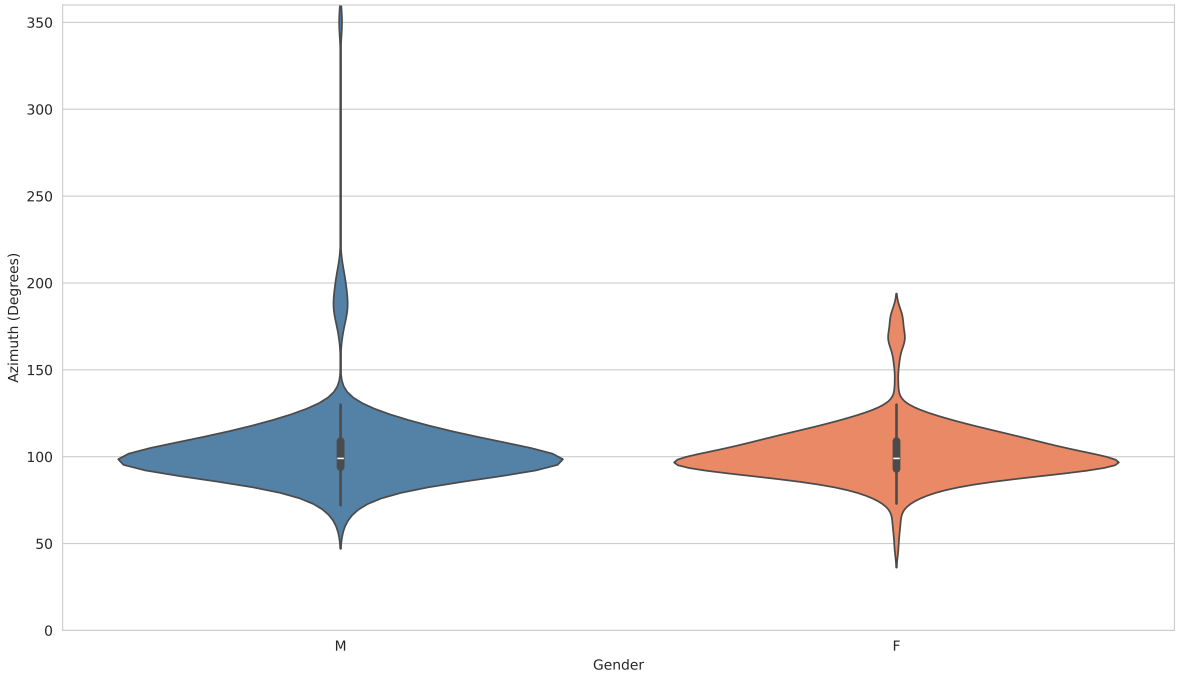

Figure 199: Grave orientation by gender.

### Burial Arm Positions by Gender

Burial arm positions are compared between genders using column-normalized percentages. Only burials with valid arm codes (positions 1–8) were included.
Based on n=733 burials with identified gender (of 1158 total), timespan $\leq$ 400 years.

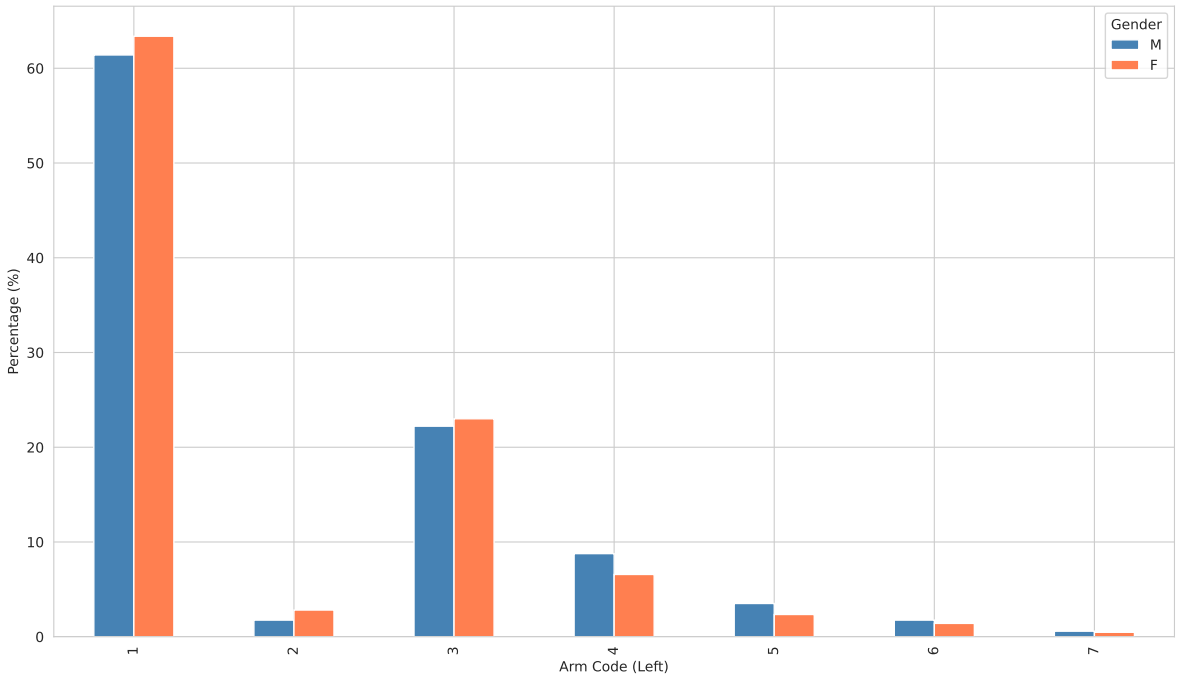

Figure 200: Left burial arm positions by gender (normalized %).

Based on n=733 burials with identified gender (of 1158 total), timespan ≤ 400 years.

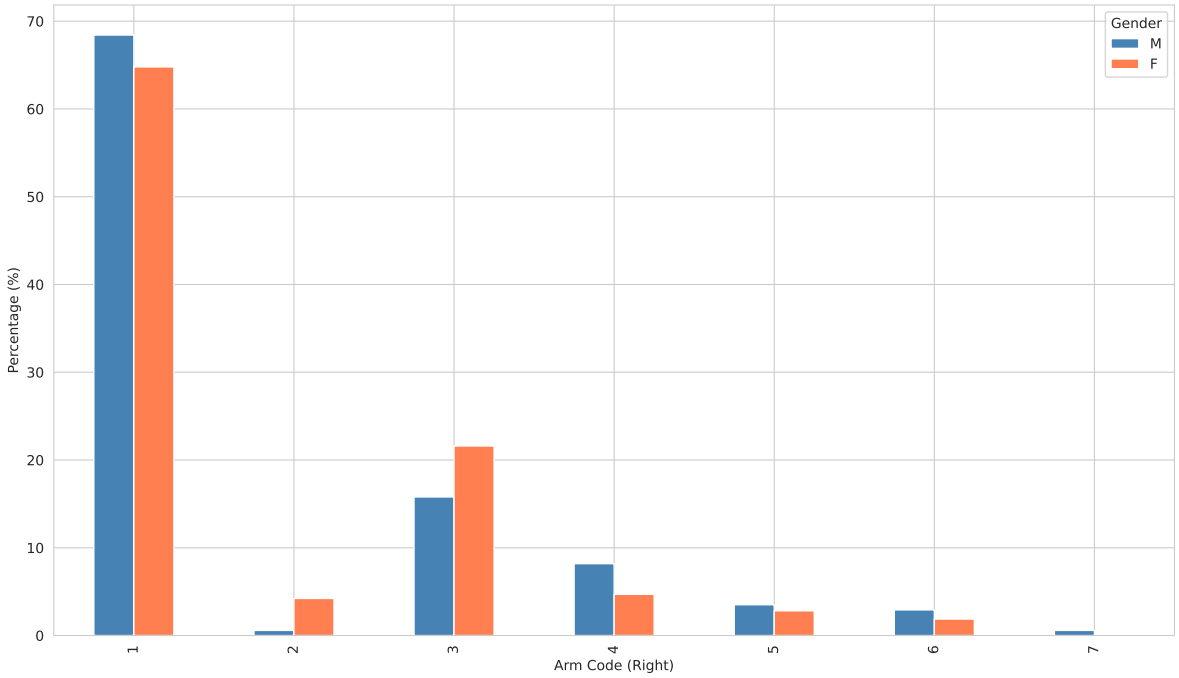

Figure 201: Right burial arm positions by gender (normalized %).

### Age at Death by Gender

Age at death is estimated as the midpoint of the recorded age range $(age_{min} + age_{max})/2$. The histogram with kernel density overlay shows age-at-death distributions by gender, while the box plot summarizes central tendency and spread.
Based on n=733 burials with identified gender (of 1158 total), timespan $\leq$ 400 years.

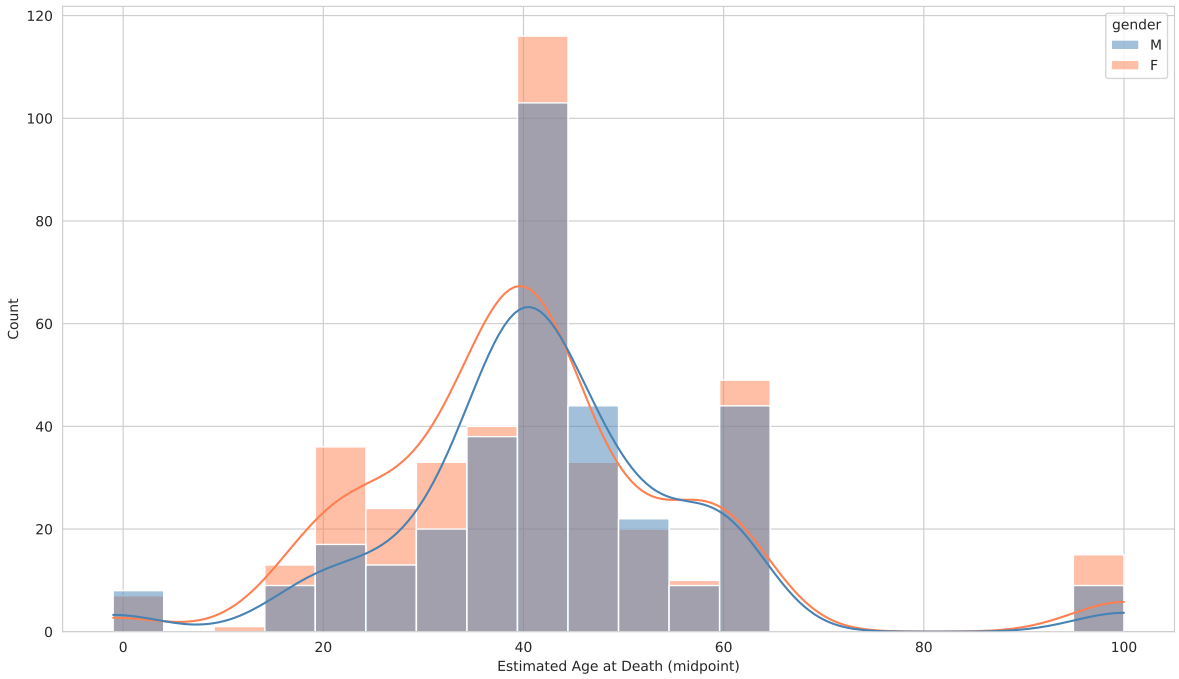

Figure 202: Age at death distribution by gender.

Based on n=733 burials with identified gender (of 1158 total), timespan ≤ 400 years.

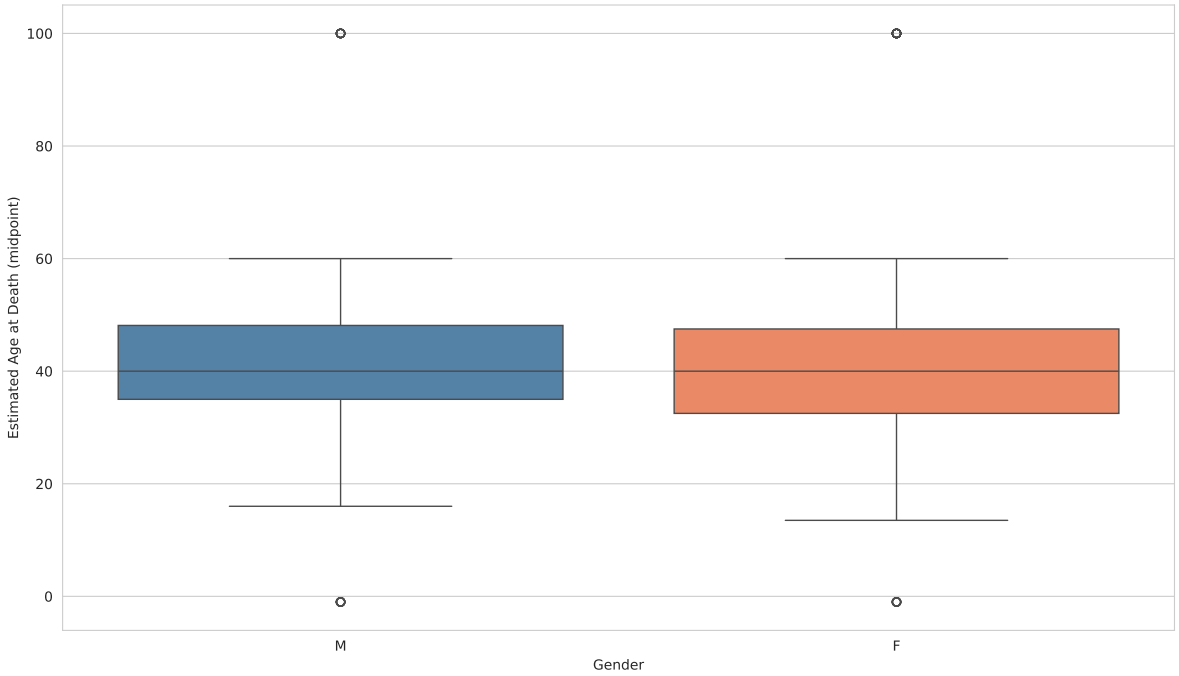

Figure 203: Age at death by gender (box plot).

Based on n=733 burials with identified gender (of 1158 total), timespan ≤ 400 years.

### Stratigraphic Sequences Catalogue

Sequences were extracted from the solved graph using `ABOVE` relations, with `CONTEMPORARY` grave links allowed to extend valid paths where present. This catalogue presents all sequences associated with each grave, rendered top-down from `T` to `G`. Graves and anchors are drawn as rectangles, while `SU` nodes are drawn as ellipses.

Based on n=2919 graves and 13116 extracted sequences.

Table 18: Stratigraphic sequence counts by grave.
