## ABSTRACT

We conducted a phytosociological study of *Quercus petraea* stands, whose herb layer is dominated by *Erica carnea* in the flysch hills of Vipavska brda and on the margins of the Vrhe plateau (southwestern Slovenia). We have determined that they are a long-term degradation stage on beech forest sites from the association *Seslerio autumnalis-Fagetum*. Based on comparisons with similar sessile oak stands from associations *Melampyro vulgati-Quercetum petraeae*, *Seslerio autumnalis-Quercetum petraeae* and *Erico carneae-Quercetum petraeae*, the studied stands are classified into the new association *Chamaecytiso hirsuti-Quercetum petraeae*. They are best differentiated from the stands of compared communities by the species *Erica carnea*, *Sorbus aria*, *Lathyrus linifolius*, *Loranthus europaeus* and *Erythronium dens-canis*. The new association is classified into the alliance *Carpinion orientalis* and order *Quercetalia pubescenti-petraeae*.

**Key words:** phytosociology, synsystematics, *Seslerio autumnalis-Fagetum*, *Chamaecytiso hirsuti-Quercetum petraeae*, *Carpinion orientalis*, degradation stage, Vipavska brda, Vrhe, Slovenia

## IZVLEČEK

Fitocenološko smo raziskali sestoje gradna (*Quercus petraea*) v flišnem gričevju Vipavskih brd in na robu planote Vrhe (jugozahodna Slovenija), v katerih v zeliščni plasti prevladuje vrsta *Erica carnea*. Ugotavljamo, da so dolgotrajeni degradacijski stadiji na rastiščih bukovega gozda iz asociacije *Seslerio autumnalis-Fagetum*. Na podlagi primerjav s podobnimi gradnovimi sestoji iz asociacij *Melampyro vulgati-Quercetum petraeae*, *Seslerio autumnalis-Quercetum petraeae* in *Erico carneae-Quercetum petraeae* preučene sestoje uvrščamo v novo asociacijo *Chamaecytiso hirsuti-Quercetum petraeae*. Od sestojev primerjanih združb jih najbolj razlikujejo vrste *Erica carnea*, *Sorbus aria*, *Lathyrus linifolius*, *Loranthus europaeus* in *Erythronium dens-canis*. Novo asociacijo uvrščamo v zvezo *Carpinion orientalis* in v red *Quercetalia pubescenti-petraeae*.

**Ključne besede:** fitocenologija, sinsistematička, *Seslerio autumnalis-Fagetum*, *Chamaecytiso hirsuti-Quercetum petraeae*, *Carpinion orientalis*, degradacijski stadij, Vipavska brda, Vrhe, Slovenija

## 1 INTRODUCTION

### 1 UVOD

The forest of the Vipavska brda in southwestern Slovenia as seen from a distance (e.g. from the Nanos plateau) gives a fairly uniform picture. A closer view, however, shows that these are secondary stands that clearly demonstrate the impact of past management. In terms of ecology – these are steep, shady flysch slopes cross-cut with streams – the highest stage of development in the primary post-glacial development in this area was probably beech forest. Individual beech trees can still be found in numerous spots, as well as many beech stands, especially on higher elevations on slopes under the Vrhe plateau and in the eastern part

of the hills towards Razdrto and Raša. We conducted a phytosociological inventory of several such beech stands that are mainly classified into the association *Seslerio autumnalis-Fagetum* (compare Dakskobler, 1997). The dominant species now is without a doubt sessile oak (*Quercus petraea*), and its stands, whose herb layer is dominated by autumn moor grass (*Sesleria autumnalis*), are classified into the association *Seslerio autumnalis-Quercetum petraeae* (Čarni et al., 2002). We were especially interested in low-growing oak coppice stands, where the herb layer is completely dominated by spring heath (*Erica carnea*). Elevation, geological bedrock, slope are similar as in beech or sessile oak stands with autumn moor grass, while the

herb layer is clearly different. Degradation and, in turn, deterioration of soil- and consequently of site conditions and changes in the species composition could have been caused by erosion (removal of soil still ongoing in several locations) and definitely also by past human activities, especially by litter gathering (Čokelj, in litt.). A phytosociological inventory was conducted for both beech and oak stands; the relevés were arranged into two tables and the results of our research are presented in this paper.

### 1.1 Ecological description of the study area

#### 1.1 Ekološki opis raziskovanega območja

The name Vipavska brda denotes the hills situated south of the Vipava river, north of the Branica river and west of the Močilnik stream (Kladnik, 2000) in southwestern Slovenia. In the east, the hills gradually continue into the Vrhe plateau between the Vipava and Raša valleys. The shady slopes of the Vipavska brda and of the Vrhe plateau above the Močilnik and Pasji rep streams are now mainly covered with forests. Settlements are located both on the plateau and in the valley. Figure 1 shows the approximate location of inventoried sessile oak stands, whose herb layer is completely dominated by spring heath (*Erica carnea*). The

elevation of the localities is between 290 m and 535 m, the aspect is distinctly shady, northern, northeastern, eastern as well as southeastern, the slope is 5° to 30°. Geological bedrock of the Vipavska brda is Eocene flysch (Buser, 1973, 2009) and the predominant soil type is eutric brown soil (Lovrenčak, 1998, Prus, in litt.).

The climate is warm, with mean annual temperature of 10°C to 12°C (Cegnar, 1998) and mean annual precipitation of between 1,400 mm and 1,600 mm (B. Zupančič, 1998). The phytosociological map of potential natural forest vegetation of Slovenia, scale 1: 400,000 (Čarni et al., 2002), indicates the study area as the association *Seslerio autumnalis-Quercetum petraeae*. According to our findings, beech forest is the potential natural vegetation of shady slopes of the Vipavska brda, especially the forest from the association *Seslerio autumnalis-Fagetum*, in part also from the association *Ornithogalo pyrenaici-Fagetum*. Stands of the association *Seslerio autumnalis-Quercetum petraeae* (see relevés 11 and 12 in Table 2) in this area are largely secondary degradation stage. Although the steep flysch slopes have always been largely wooded, the military map from the second half of the 18th century (Rajšp and Trpin, 1997) indicates relatively large viticultural areas also on the shady slopes, at least in the Pasji rep

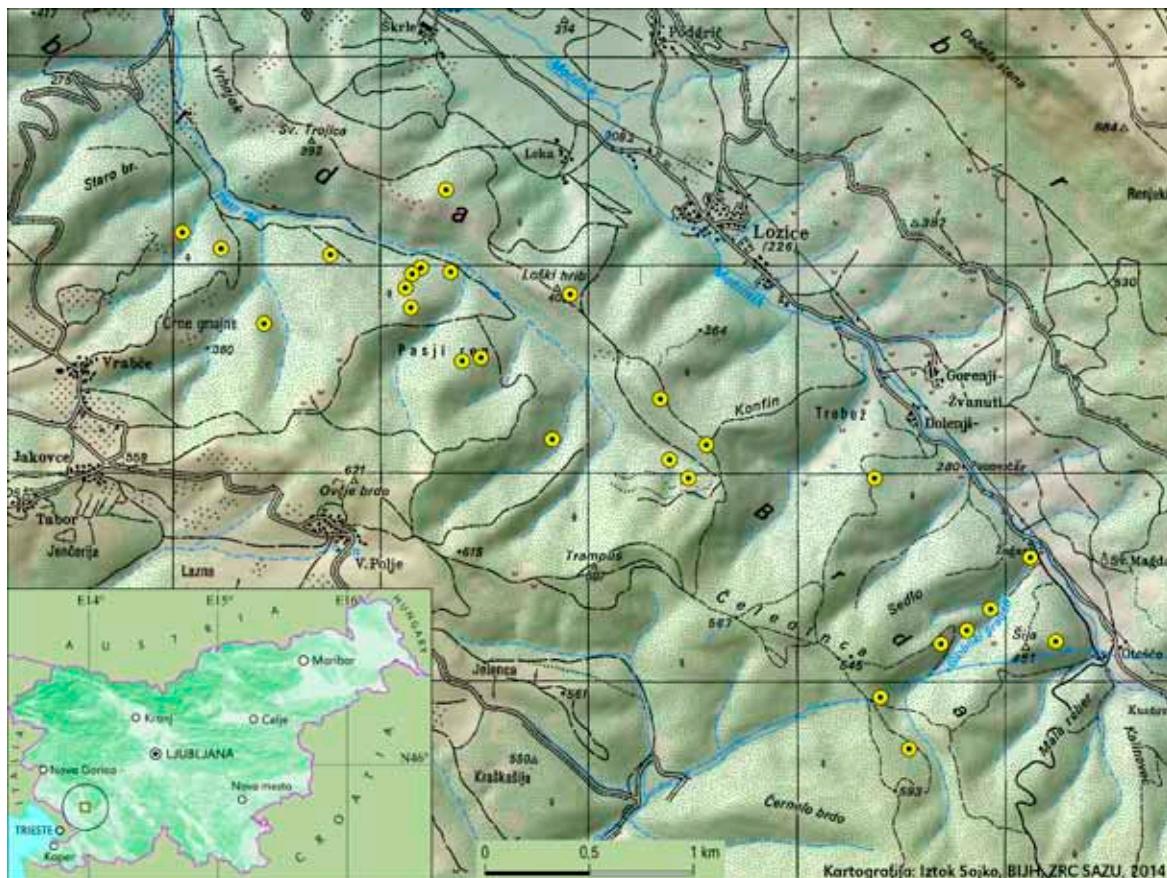

Fig. 1: Approximate localities of inventoried sessile oak stands in the Vipavskih brdih

Slika 1: Približna nahajališča raziskanih gradnovih sestojev v Vipavskih brdih

valley. Pioneer stands of various deciduous trees occur elsewhere too, especially in gullied slopes with deep soil. They frequently feature wild cherry (*Prunus avium*) – see relevé No. 13 in Table 2. Sites on what was once clearly agricultural land are increasingly overgrown by black locust (*Robinia pseudoacacia*).

## 2 MATERIALS AND METHODS

### 2 MATERIALI IN METODE

Vegetation in the Vipavska brda was researched applying the Central-European phytosociological method (Braun-Blanquet, 1964). A total of 39 relevés were made and entered into the FloVegSi database (Seliškar et al., 2003). Combined cover-abundance values were transformed into numerical values 1– 9 (van der Maarel, 1979). Numerical comparisons were conducted with the software package SYN-TAX (Podani, 2001). Relevés were arranged into two analytic tables (Tables 1 and 2) based on hierarchical classification. We integrated the results of the (unweighted) pair group method with arithmetic mean “(Unweighted) average linkage” – UPGMA, where Wishart's similarity ratio was applied. Phytosociological groups (= groups of diagnostic species) were formed on the basis of our own criteria, but with consideration of several authors (Aeschimann et al., 2004, Poldini, 1982, 1988, 1989, Zupančič, 1999). Similar oak communities from the sub-Mediterranean part of Slovenia (Poldini, 1982, Zupančič, 1999) and from serpentine areas in Bosnia (Krause and Ludwig, 1957, Ritter-Studnička, 1970) were compared through hierarchical classification and two-dimensional ordination (principal coordinates analysis, PCoA), as well as on the basis of Sørensen's coefficient of floristic similarity (Sørensen, 1948) and analysis of percentage of diagnostic species of syntaxonomic groups. The nomenclature source for the names of vascular plants is Mala flora Slovenije (Martinčič et al., 2007). Martinčič (2003, 2011) is the nomenclature source for the names of mosses, Šilc and Čarni (2012) for the names of syntaxa (with the exception of the names of the class *Querco-Fagetea* Braun-Blanquet et Vlieger in Vlieger 1937 and alliance *Carpinion orientalis* Horvat 1958) and Urbančič et al. (2005) for the names of soil types.

## 3 RESULTS AND DISCUSSION

### 3 REZULTATI IN RAZPRAVA

#### 3.1 Description of soils in the researched stands

##### 3.1 Opis tal v preučenih sestojih

Soil conditions were described on the basis of the sample that was obtained in the Pasji rep valley and

analysed in the laboratory of the Slovenian Forestry Institute, as well as on the basis of the public data provided by the Infrastructural Centre for Pedology and Plant Protection at the Department of Agronomy of Biotechnical Faculty in Ljubljana, which were interpreted for us by Tomaž Prus (in litt.). Convex slopes with relatively shallow soil prevail, in places showing signs of erosion (leaching). The dominant soil type is lessivé eutric brown soil. Upper horizons are strongly acid (pH H<sub>2</sub>O 4.8, pH CaCl<sub>2</sub> 3.8 to 4.0), the humus type is moder (C/N ratio exceeds 20). Soil properties change with depth and pH increases considerably. This indicates past practices on surface soil horizons. Litter gathering is one of the likely reasons that accelerated the process of soil base cation (Ca, Mg, K) leaching. Although characteristic for alkaline soils, *Erica carnea* can thrive also on soils that have gradually become acid. In the event of further soil degradation (acidification), it would be replaced by *Calluna vulgaris*, which has only been found in isolated spots in our relevés. Abundant occurrence of *Erica carnea* in the Vipavska brda can be attributed to the distinctly shady aspect, i.e. local climate factors, erosion-associated processes on convex slopes and to past litter gathering.

#### 3.2 Stand description and species composition (Table 1)

##### 3.2 Oznaka sestojev in vrstna sestava (preglednica 1)

Pole- and mature sessile oak stands prevail on 39 researched plots; their diameter at breast height is between 25 cm and 35 cm and tree height between 10 m and 16 m. Many of them are of coppice origin. Frequent occurrence of the parasite *Loranthus europaeus* in sessile oak crowns indicates relatively poor vitality of sessile oak on these sites. The upper tree layer is admixed with individual trees of *Fagus sylvatica*, *Castanea sativa* and *Sorbus aria*, very rarely also by *Pinus nigra* (sub-spontaneously), *Betula pendula*, *Ostrya carpinifolia*, *Sorbus aucuparia* and *Pinus sylvestris*. The alien species *Robinia pseudoacacia* was recorded in the tree layer on one of the plots. The species that frequently occur in the lower tree layer and in the upper shrub layer include *Fraxinus ornus*, *Sorbus aria*, *S. torminalis*, *Juniperus communis*, in places also *Castanea sativa* and *Fagus sylvatica*, and only rarely *Laburnum alpinum*, *Pyrus pyraster*, *Amelanchier ovalis* and *Crataegus monogyna*. In the shrub layer, we inventoried the taxa *Sorbus graeca* and *S. austriaca*, but our determination is not completely reliable. Above Veliki graben above Otošče we found a rare hybrid between *Sorbus aria* and *S. torminalis* = *Sorbus latifolia* s. lat. In addition to the dominating *Erica*

*carnea*, the taxon *Molinia caerulea* subsp. *arundinacea*, in places also the species *Convallaria majalis*, *Serratula tinctoria* and *Vaccinium myrtillus*, on several spots also *Pteridium aquilinum*, have a higher medium coverage. Common grasses include *Sesleria autumnalis*, *Avenella flexuosa* and *Calamagrostis arundinacea*; *Luzula luzuloides* is also frequent. Species with high constancy (more than 50%) in the herb layer are also *Chamaecytisus hirsutus*, *Tanacetum corymbosum*, *Hieracium racemosum*, *H. sabaudum*, *H. murorum*, *Genista pilosa*, *Platanthera bifolia* and *Erythronium dens-canis*. Common species in the moss layer are *Hypnum cupressiforme*, *Thuidium tamariscinum* and *Polytrichum formosum* (= *Polytrichastrum formosum*), with *Leucobryum glaucum* observed on several plots.

### 3.3 Comparison with preserved beech stands (Table 2)

#### 3.3 Primerjava z ohranjenimi bukovimi sestoji (preglednica 2)

Table 2 comprises 13 relevés from the same area (Vipavska brda, Vrhe), but with a different composition of the tree layer. Ten relevés (1 to 10) are classified into the association *Seslerio autumnalis-Fagetum*, two are a degradation stage with dominant sessile oak on a beech site (relevés 11 and 12, both classified into the association *Seslerio autumnalis-Quercetum petraeae*). Relevé No. 13 characterises a pioneer forest on former agricultural land dominated by *Prunus avium*, with individual specimens of *Ostrya carpinifolia*, *Acer pseudoplatanus*, *A. campestre* and *Robinia pseudoacacia*. We assume this is a pioneer stage on potential sites of the association *Ornithogalo pyrenaici-Fagetum*. Comparison of 26 relevés of sessile oak forest with ten relevés of the beech forest from the association *Seslerio autumnalis-Fagetum* from the same area indicates substantial differences not only in the tree layer, but also in the herb layer. In beech stands, it is usually dominated by *Sesleria autumnalis*, there are clearly more mesophilous species, character species of the order *Fagetalia sylvaticae* (see Tables 2 and 4). The soil is deeper, less acid and in places also moister.

### 3.4 Synsystematic classification 3.4 Sinsistematska opredelitev

Natural characteristics (flysch slopes), phytogeographical position and origin (secondary community) of the studied stands are similar to the conditions in which sessile oak stands of the syntaxon *Melampyro vulgati-Quercetum petraeae* var. geogr. *Fraxinus ornus* (Puncer and Zupančič, 1979, Zupančič, 1994) grow in the hills of Brkini. We conducted a comparison between

19 relevés of this association and our relevés; floristic similarity according to Sørensen (1948) is about 56%, which allows for classification into the same association, but new subassociation *Melampyro-Quercetum ericetosum carneae*. Such classification is conditionally supported also by the presence of diagnostic species from the association *Melampyro-Quercetum* in the studied stands in the Vipavska brda. In addition to sessile oak, *Luzula luzuloides*, *Hieracium sabaudum* and the geographical differential species *Avenella flexuosa* (= *Deschampsia flexuosa*) also frequently occur in these stands. *Melampyrum pratense* subsp. *vulgatum* and *Chamaecytisus supinus* occur with considerably lower frequency and medium coverage, whereas *Lembotropis nigricans* and geographical differential species *Orobanche nana* (*O. ramosa* subsp. *nana*) were not recorded. There are obvious differences in the proportion of diagnostic species (Table 4). The studied stands comprise a considerably higher proportion of thermophilous species of the order *Quercetalia pubescenti-petraeae* and class *Erico-Pinetea* and a much smaller proportion of acidophilous species of the order *Quercetalia roboris* and class *Vaccinio-Piceetea* than the stands of the association *Melampyro-Quercetum*. Soil conditions are different. Dystric brown soils prevail in the stands of the association *Melampyro-Quercetum*, whereas the soil in our stands is eutric, although frequently leached. The fundamental difference is in potentially natural vegetation. In terms of the association *Melampyro-Quercetum*, this is most frequently a moderate acidophilous beech-oak forest from the association *Castaneo-Fagetum sylvaticae*, in our case the sub-Mediterranean beech forest from the association *Seslerio autumnalis-Fagetum*. This is also the basis for classification into two different orders. The association *Melampyro-Quercetum* is classified into the alliance *Quercion roboris* (or *Genisto germanicae-Quercion roboris*) and into the order *Quercetalia roboris*, while the studied stands with their floristic composition are classified into the alliance *Carpinion orientalis* and into the order *Quercetalia pubescenti-petraeae*. If these stands were classified as the new subassociation *Melampyro-Quercetum petraeae ericetosum carneae* it should be classified into the same alliance as the previously described subassociations (Puncer and Zupančič, 1979), i.e. into the alliance *Quercion roboris* (or *Genisto germanicae-Quercion roboris*), which does not correspond to its full floristic composition. We therefore conducted additional comparisons with another two syntaxa, the association *Seslerio autumnalis-Quercetum petraeae* (Zupančič, 1999, Table 5, Poldini, 1982, Table 4, columns 27–34) and with the association *Erico carneum*

*ae-Quercetum petraeae* (Krause and Ludwig, 1957: 118–120, Ritter-Studnička, 1970: 114–115, Beus, 1997: 94–95). We also made a synthetic table (Table 3) with six columns and compared them with hierarchical classification and two-dimensional ordination (Figures 2 and 3). In terms of floristics, our stands are most similar to the stands of the association *Melampyro-Quercetum petraeae*. Floristic similarity with the association *Seslerio autumnalis-Queretum petraeae* according to Sørensen (1948) is already lower at about 45%. Similarity is only slightly higher (47%) with the most acidophilous form of this association described by Poldini (1982) as *Seslerio autumnalis-Queretum petraeae avenelletosum flexuosae*. It is differentiated by *Castanea sativa*, *Luzula luzuloides*, *Avenella flexuosa* and some other species. Poldini (*ibid.*) described two variants: the variant with *Erica carnea* on sites with less acid soil and the variant with *Polytrichum formosum*, *Leucobryum glaucum*, *Genista germanica* and *Dicranum scoparium* on more acid soil. He found such stands both on flysch and limestone. The tree layer is frequently dominated by Turkey oak (*Quercus cerris*). Poldini attributed the increased soil acidity to the past litter gathering. Despite certain similarities with the studied stands in the Vipavska brda (occurrence of *Erica carnea*, but with less medium coverage, and of some other acidophilous species except *Vaccinium myrtillus*), the dendrogram (Figures 2 and 3) shows the stands of the subassociation *-avenelletosum flexuosae* grouping with stands of other forms of the association *Seslerio autumnalis-Queretum petraeae* and not with our community.

With consideration of the dominant species of the tree and herb layers, the studied stands could be classified into the association *Erico carneae-Quercetum petraeae* that was described in northern Bosnia (Krause and Ludwig, 1957: 90–91 and Table 1, column 3 on pages 118–120, Horvat, 1959: 30, Ritter-Studnička, 1970), but in very different ecological conditions, on serpentine bedrock (in western Bosnia the oak stands with *Erica carnea* were described also on Permian sandstones and on dystric soils and were classified into the syntaxon *Betulo-Quercetum petraeae ericotosum* – Fabijanić et al., 1963, Stefanović, 1984). Stands of this association are syndynamically closely related to the black and red pine on serpentinite (see also Horvat et al., 1974: 461) and their progressive development also leads to the (fir)beech forest. Floristic similarity of 23 relevés from the synthetic table of the association *Erico-Quercetum petraeae* Krause et Ludwig ex Horvat 1959 (the correct author citation, Theurillat, in litt.) – Ritter-Studnička (1970: 114–115) with our stands is

only 20% according to Sørensen (1948), while floristic similarity of 5 relevés from the synthetic table of the same association (Krause and Ludwig, *ibid.*) is slightly higher (31%), which does not allow for its classification into the same association. In addition, Zupančič et al. (1986: 12) classify the association *Erico-Quercetum petraeae* into the alliance *Quercion robori-petraeae* = *Quercion roboris* and into the order *Quercetalia robori-petraeae* = *Quercetalia roboris*, while we classify the studied stands into the order *Quercetalia pubescenti-petraeae*. Floristic dissimilarity is further confirmed by hierarchical classification (Figures 2 and 3).

Based on these comparisons, we decided to classify sessile oak stands from the Vipavska brda into the new association *Chamaecytiso hirsuti-Quercetum petraeae* ass. nov. *hoc loco*. Its diagnostic species are *Quercus petraea* (the edifier of all four compared communities that characterises the newly described association against the primary association *Seslerio autumnalis-Fagetum*), *Erica carnea*, *Sorbus aria*, *Sesleria autumnalis*, *Chamaecytisus hirsutus*, *Lathyrus linifolius*, *Loranthus europaeus* and *Erythronium dens-canis*. These species undoubtedly differentiate the studied stands both from floristically slightly similar stands of the associations *Seslerio autumnalis-Quercetum petraeae* and *Melampyro-Quercetum petraeae* as well as from physiognomically similar (with dominant *Erica carnea* in the herb layer) stands of the association *Erico-Quercetum petraeae* in Bosnia. The differential species that distinguish them from the stands of the association *Seslerio-Quercetum* are *Loranthus europaeus*, *Lathyrus linifolius* and *Erythronium dens-canis*, partly also *Erica carnea* and *Sorbus aria*. The species that differentiate them from the stands of the association *Melampyro-Quercetum* are *Sorbus aria*, *Sesleria autumnalis*, *Chamaecytisus hirsutus*, *Lathyrus linifolius*, *Erythronium dens-canis* and *Loranthus europaeus*, and the species that differentiate them from the stands of the association *Erico-Quercetum* are *Sorbus aria*, *Sesleria autumnalis*, *Lathyrus linifolius* and *Loranthus europaeus*. The diagnostic species characterise the new association both ecologically (*Erica carnea*, *Sorbus aria*, *Chamaecytisus hirsutus*, *Lathyrus linifolius*, *Loranthus europaeus*) and phytogeographically (especially *Sesleria autumnalis* and *Erythronium dens-canis*). The nomenclature type of the new association, *holotypus*, is relevé No. 5 in Table 1.

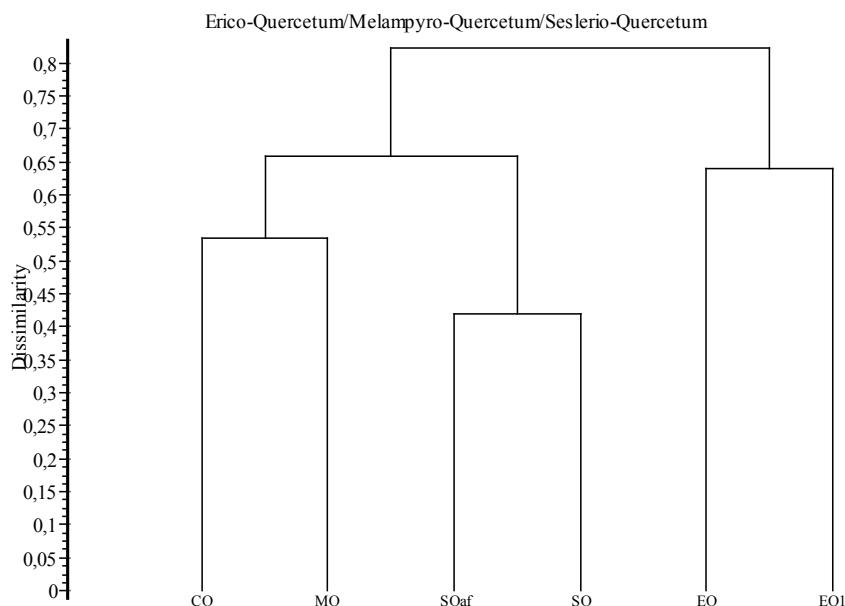

#### 4 CONCLUSIONS

#### 4 ZAKLJUČKI

Stands of *Quercus petraea* with *Chamaecytisus hirsutus* and *Erica carnea* on shady slopes of the Vipavska

brda under the Vrhe plateau are an easily recognised degradation stage on potential sites of beech forest from the association *Seslerio autumnalis-Fagetum* and are also easily distinguishable from other stands. The forest's surface area is estimated at between 500 ha and 1,000 ha (so far, it has been mapped as the association *Melampyro vulgati-Quercetum petraeae*, Reščič, in litt.). Stands of this stage are mainly distributed in the Karst forest management region, in the forest management unit Vrhe and on a smaller area also in the Ajdovščina forest management unit within the Tolmin forest management region. Progressive development back into the beech forest has been very slow. Now, in the absence of human impact (such as litter gathering), it is hindered by natural factors (convex slopes subject to erosion) and by the fact that due to the warm climate beech in this area occurs on the edge of its natural distribution area. It therefore makes sense to treat these stands at the level of the association *Chamaecytiso hirsuti-Quercetum petraeae* and to make sure that their

role of protection against erosion is considered in forest management practice. They play a significant role also as a biotope, i.e. as a site of the rare hybrid *Sorbus latifolia* s. lat. (see Avdibegović et al., 2013), protected species *Erythronium dens-canis*, *Platanthera bifolia*, *P. chlorantha*, *Lilium martagon*, *Cephalanthera longifolia*, *Neottia nidus-avis*, *Sedum maximum* (Anon., 2004) and of *Leucobryum glaucum*, a moss species of conservation concern (Anon., 2002). In terms of floristics and site conditions, the stands of the new association slightly resemble the stands of associations *Melampyro vulgate-Quercetum petraeae*, *Seslerio autumnalis-Quercetum petraeae* and *Erico carneae-Quercetum petraeae*, but also distinctly differ from them in terms of syndynamics, certain ecological factors and in the occurrence of several species. They are characterised by the shady aspect, flysch bedrock, lessivé eutric brown soils, the sub-Mediterranean climate and differential species such as *Erica carnea*, *Sorbus aria*, *Lathyrus linifolius*, *Loranthus europaeus* and *Erythronium dens-canis*.

Classification of the new association into higher syntaxonomical units is as follows:

Class: *Querco-Fagetea* Br.-Bl. et Vlieger in Vlieger 1937

Order: *Quercetalia pubescenti-petraeae* Klika 1933

Alliance: *Carpinion orientalis* Horvat 1958

Suballiance: *Seslerio autumnalis-Ostryenion* Blasi, Di Pietro & Filesi 2004 = *Ostryo-Carpinenion orientalis* Horvat (1954) 1958 nom. illeg.

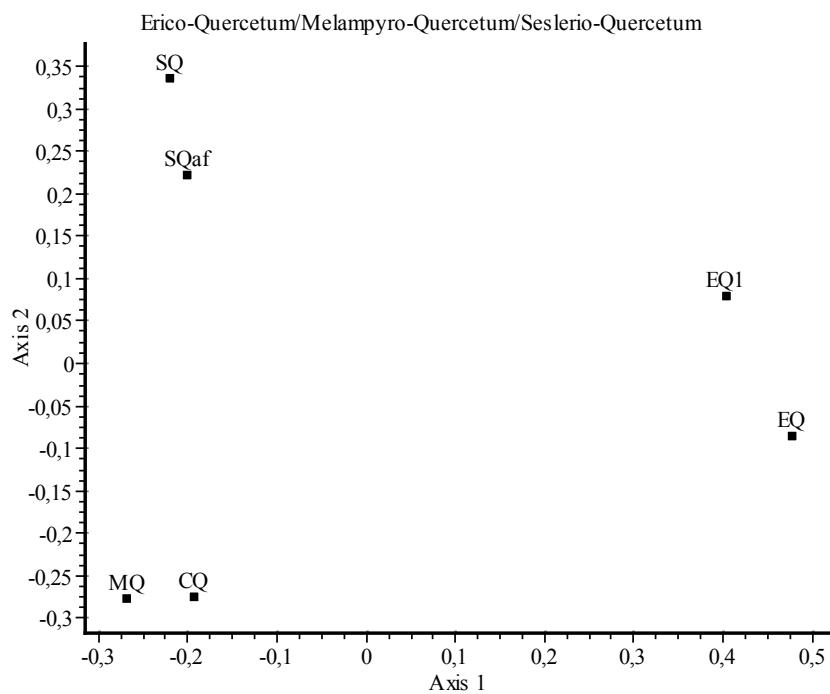

Association: *Chamaecytiso hirsuti-Quercetum petraeae* ass. nov. hoc loco

## 5 POVZETEK

### 5 SUMMARY

Po standardni srednjeevropski metodi smo fitocenološko preučili sestoje gradna (*Quercus petraea*) v flišnem gričevju Vipavskih brd in na robu planote Vrhe (jugozahodna Slovenija), v katerih v zeliščni plasti prevladuje vrsta *Erica carnea* (slika 1, preglednica 1). Uspevajo na položnih do strmih osojnih pobočjih, na nadmorski višini od 250 m do 550 m. Prevladujoči talni tip so evtrična rjava tla, ki so pogosto izprana. Potencialno naravna vegetacija osojnih pobočij tega gričevja je bukov gozd iz asociacije *Seslerio autumnalis-*

*Fagetum*, kar potrjujejo nekateri še ohranjeni sestoji, ki smo jih prav tako fitocenološko popisali (preglednica 2). Zdaj prevladujoče sestoje gradna uvrščamo v asociacijo *Seslerio autumnalis-Quercetum petraeae*. Nizki panjevski hrastovi sestoji s spomladansko reso uspevajo v podobnih rastiščnih razmerah kot sestoji bukve ali gradna z jesensko vlovino, a imajo očitno različno zeliščno plast. Degradacijo in s tem poslabšanje talnih in posledično rastnih razmer in spremembo vrstne seставne je povzročila erozija (odnašanje prsti, na več krajih jo vidimo še zdaj) in človekova pretekla dejavnost, predvsem steljarjenje. To se kaže v zgornjih horizontih tal, ki so precej kisli (pH H<sub>2</sub>O 4,8, pH CaCl<sub>2</sub> 3,8 do 4,0), oblika humusa je prhnina (razmerje C/N je nad 20). Z globino se lastnosti tal spremenijo in je pH precej višji. Steljarjenje je eden izmed verjetnih razlogov, ki je posledično pospešil procese izpiranja bazično delujočih kationov (Ca, Mg, K). Vrsta *Erica carnea* je sicer značilna za bazična tla, vendar lahko dobro uspeva tudi na tleh, ki so v teku razvoja postala kisla. Preučene hrastove sestoste smo primerjali s podobnimi gradnovimi združbami iz asociacij *Melampyro vulgati-Quercetum petraeae*, *Seslerio autumnalis-Quercetum petraeae* in *Erico carnea-Quercetum petraeae* in ugotovili največjo

**Fig. 3:** Two-dimensional scatter diagram of stands of the syntaxa *Chamaecytiso hirsuti-Quercetum petraeae* (CQ), *Melampyro-Quercetum petraeae* (MQ), *Seslerio autumnalis-Quercetum petraeae* (SQ), *Seslerio autumnalis-Quercetum petraeae avenelletosum flexuosae* (SQaf) and *Erico-Quercetum petraeae* (EQ, EQ1) from southwestern Slovenia and Bosnia, PCoA, similarity ratio

**Slika 3:** Dvorazsežni ordinacijski diagram sestojev sintaksonov *Chamaecytiso hirsuti-Quercetum petraeae* (CQ), *Melampyro-Quercetum petraeae* (MQ), *Seslerio autumnalis-Quercetum petraeae* (SQ), *Seslerio autumnalis-Quercetum petraeae avenelletosum flexuosae* (SQaf) in *Erico-Quercetum petraeae* (EQ, EQ1) iz jugovzhodne Slovenije in Bosne, PCoA, količnik podobnosti »similarity ratio«

floristično podobnost s sestoji asociacije *Melampyro vulgati-Quercetum petraeae* iz flišnih Brkinov. Od njih se razlikujejo v talnih razmerah, sestavi po skupinah diagnostičnih vrst (preglednica 5), po izvirni združbi, ki je v primeru asociacije *Melampyro-Quercetum* kisloljubno bukovje (*Castaneo-Fagetum sylvaticae*), in po pripadnosti višjim sintaksonomskim enotam (asociacijo *Melampyro-Quercetum* uvrščamo v zvezo *Quercion roboris* in v red *Quercetalia roboris*). Ekološko nekoliko podobni so tudi sestoji subasociacije *Seslerio autumnalis-Quercetum petraeae avenelletosum flexuosae*, a je njihova floristična sestava že precej drugačna, kar potrjuje hierarhična klasifikacija (sliki 2 in 3). Ta kaže tudi na očitno floristično različnost s sestoji asociacije *Erico-Quercetum petraeae*, ki so jo opisali v Bosni, na serpentinski podlagi. Ti sestoji imajo kljub podobnosti v dominantnih vrstah drevesne in zeliščne plasti, gradnu in spomladanski resi, drugačno sindinamiko in so povezani z združbami črnega in rdečega bora. Na podlagi teh primerjav drugotne gradnove sestoje iz Vipavskih brd uvrščamo v novo asociacijo *Chamaecytiso hirsuti-Quercetum petraeae ass. nov. hoc loco* (zveza *Carpinion orientalis*, red *Quercetalia pubescent-petraeae*). Njen nomenklturni tip, *holotypus*, je popis št. 5 v preglednici 1. Njene diagnostične vrste so *Quercus petraea*, *Erica carnea*, *Sorbus aria*, *Sesleria autumnalis*, *Chamaecytisus hirsutus*, *Lathyrus linifolius*, *Loranthus europaeus* in *Erythronium dens-canis*. Sestoji novo opisane asociacije so lahko prepoznaven in od drugih sestojev lahko ločljiv degradacijski stadij na potencialnih rastiščih bukovega gozda iz asociacije *Seslerio autumnalis-Fagetum*. Njegova površina ni zanemarljiva in jo ocenjujemo med 500 ha in 1000 ha. Razširjeni so v Kraškem gozdnogospodarskem območju, v gozdnogospodarski enoti Vrhe in na manjši površini tudi v Tolminskem gozdnogospodarskem območju, v gozdnogospodarski enoti Ajdovščina. Progresivni razvoj nazaj v bukov gozd je zelo počasen. Zdaj ko ni več človekovih vplivov (na primer steljarjenja), ga zavirajo naravni dejavniki (izbokla pobočja, izpostavljeni eroziji) in dejstvo, da je bukev tu zaradi toplega podnebja na robu svojega naravnega areala.

## 6 ACKNOWLEDGEMENTS

### 6 ZAHVALA

Oak forest research in the Vipava valley was partly conducted within the framework of the target research project Updating of the vegetation system for the forest management planning purposes (V4-1141), funded by the Slovenian Research Agency and Ministry of Agriculture and the Environment. Within the scope of this project, the Slovenian Forestry Institute conducted

an analysis of the soil sample. I am sincerely grateful to Mag. Tomaž Prus and Dr. Milan Kobal for their help in the interpretation of soil conditions in the stands of the studied community. Matej Reščič and Klavdijo Čokelj helped me with their advice on the forest cover and the condition of forests on both the Vrhe plateau and in the hills of Vipavska brda. I am also grateful to Dr. Metka Culiberg, Prof. Dr. Andraž Čarni and Prof. Dr. Sead Vojniković for helping me to find and obtain relevant literature sources, as well as to Dr. Lado Kutnar and Dr. Andrej Rozman for valuable improvements of the text. I owe special thanks to Prof. Dr. Jean-Paul Theurillat for the literature he so kindly provided and for his advice on the correct author citation of the association *Erico-Quercetum petraeae*. Iztok Sajko prepared Figure 1 for print. English translation by Andreja Šalamon Verbič.
